Developing a Machine Learning Model for Loan Approval Prediction

1. Introduction Loan approval prediction is a critical task for financial institutions to assess the creditworthiness of applicants. By leveraging machine learning (ML), banks can automate the decision-making process, reduce manual errors, and provide faster loan processing. This report outlines the key steps for developing a robust ML model for loan approval prediction.

2. Problem Statement The goal is to predict whether a loan application will be approved or rejected based on an applicant's financial and demographic data. The problem is formulated as a binary classification task where the target variable is "Loan Status" (Approved or Not Approved).

3. Dataset Description Typical datasets for loan approval prediction include the following features and taken from [UCI Machine Learning Repository](#) :

- **Applicant Information:**
 - Gender
 - Marital Status
 - Education Level
 - Dependents
- **Financial Data:**
 - Applicant Income
 - Co-applicant Income
 - Loan Amount Requested
 - Loan Term
 - Credit History
- **Property Information:**
 - Property Area (Urban, Semi-Urban, Rural)

The dataset should be divided into:

- Training set (90%)
- Test set (10%)

4. Data Preprocessing

4.1. Handling Missing Values

- Impute missing numerical values using mean or median.
- Impute categorical values with the mode

4.2. Encoding Categorical Variables

- Convert categorical variables into numerical format using techniques like label encoding.

4.3. Feature Scaling

- Apply normalization or standardization to numerical features to ensure all features contribute equally to the model.

5. Exploratory Data Analysis (EDA)

- Analyze correlations between features and the target variable.
- Identify patterns and trends using scatter plots and heatmaps.

6. Model Selection

6.1. Algorithms

- Logistic Regression
- Decision Trees
- Random Forests

6.2. Model Evaluation Metrics

- Mean Absolute Error
- Mean Squared Error
- Root Mean Squared Error
- R2 Score

7. Implementation Steps

7.1. Data Splitting

- Split the preprocessed dataset into training, validation, and test sets.

7.2. Model Training

- Train multiple models and tune hyperparameters using grid search or random search.

7.3. Model Validation

- Use cross-validation to ensure model generalization.

7.4. Model Testing

- Evaluate the best-performing model on the test set.

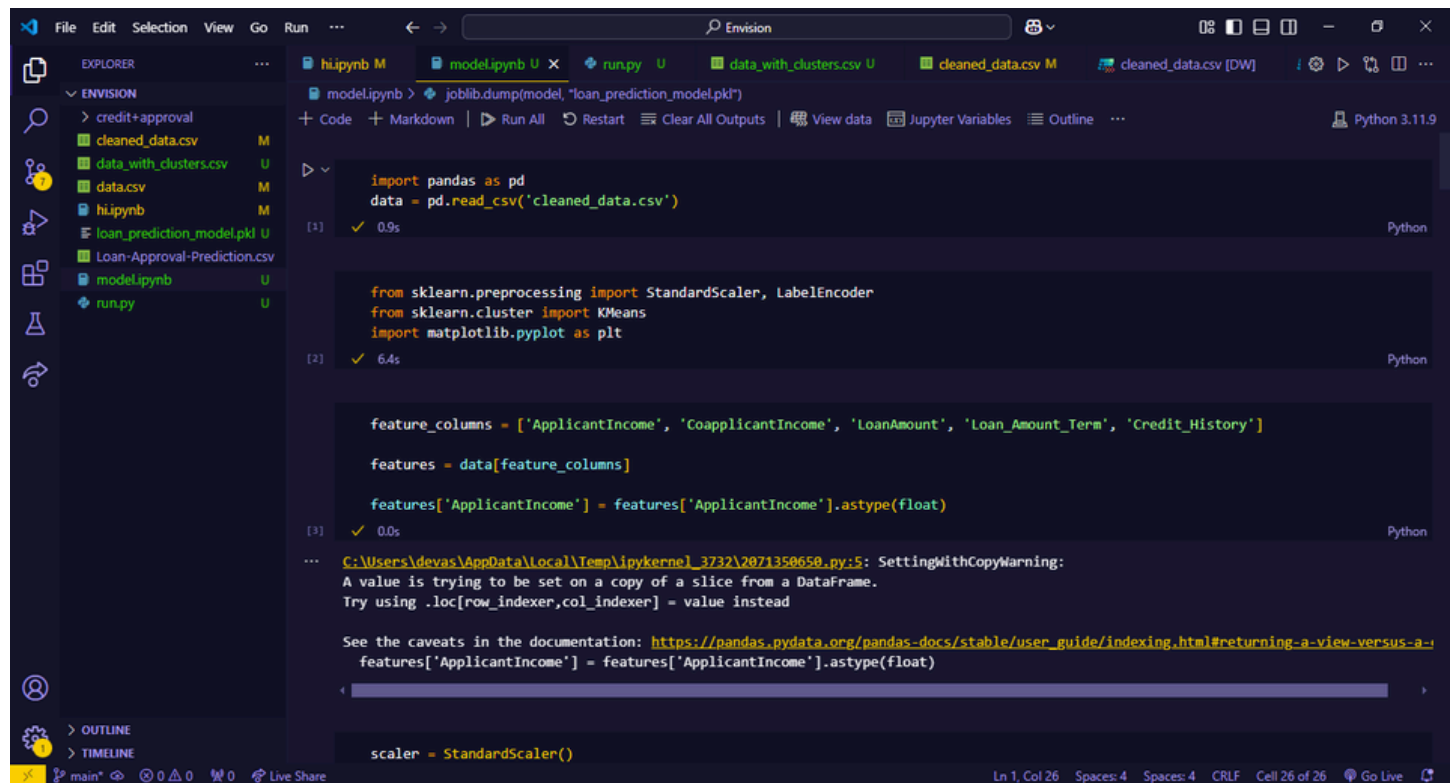

8. Deployment

- Integrate the trained model into a web, but due to lack of Credit-card details we can't able to create AWS account and can't able to deploy
- Use platforms like Flask to serve predictions in real time.

9. Conclusion Developing a machine learning model for loan approval prediction involves careful data preprocessing, model selection, and validation. By leveraging advanced algorithms and ensuring proper deployment strategies, financial institutions can enhance their decision-making processes, reduce operational costs, and improve customer satisfaction.

Given Below is the detailed implementation:

Imported the cleaned data file and also import sklearn for clustering and scaling

```
modelLipynb > joblib.dump(model, "loan_prediction_model.pkl")
+ Code + Markdown | ▶ Run All ⏮ Restart ⏻ Clear All Outputs | 📄 View data 📊 Jupyter Variables 📖 Outline ... Python 3.11.9

import pandas as pd
data = pd.read_csv('cleaned_data.csv')
[1] ✓ 0.9s Python

from sklearn.preprocessing import StandardScaler, LabelEncoder
from sklearn.cluster import KMeans
import matplotlib.pyplot as plt
[2] ✓ 6.4s Python

feature_columns = ['ApplicantIncome', 'CoapplicantIncome', 'LoanAmount', 'Loan_Amount_Term', 'Credit_History']
features = data[feature_columns]

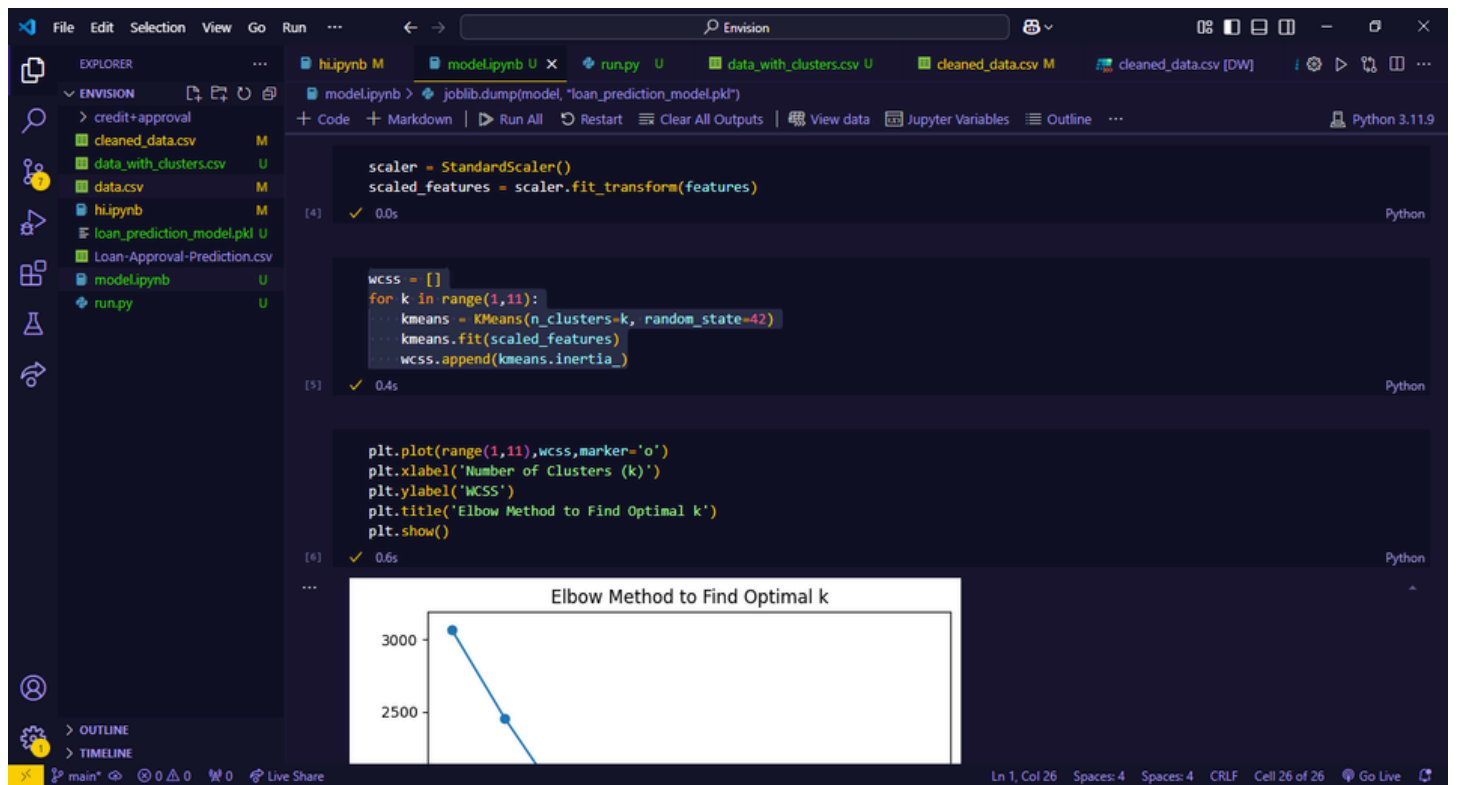

features['ApplicantIncome'] = features['ApplicantIncome'].astype(float)
[3] ✓ 0.0s Python

... C:\Users\devas\AppData\Local\Temp\ipykernel_3732\2071350650.py:5: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead

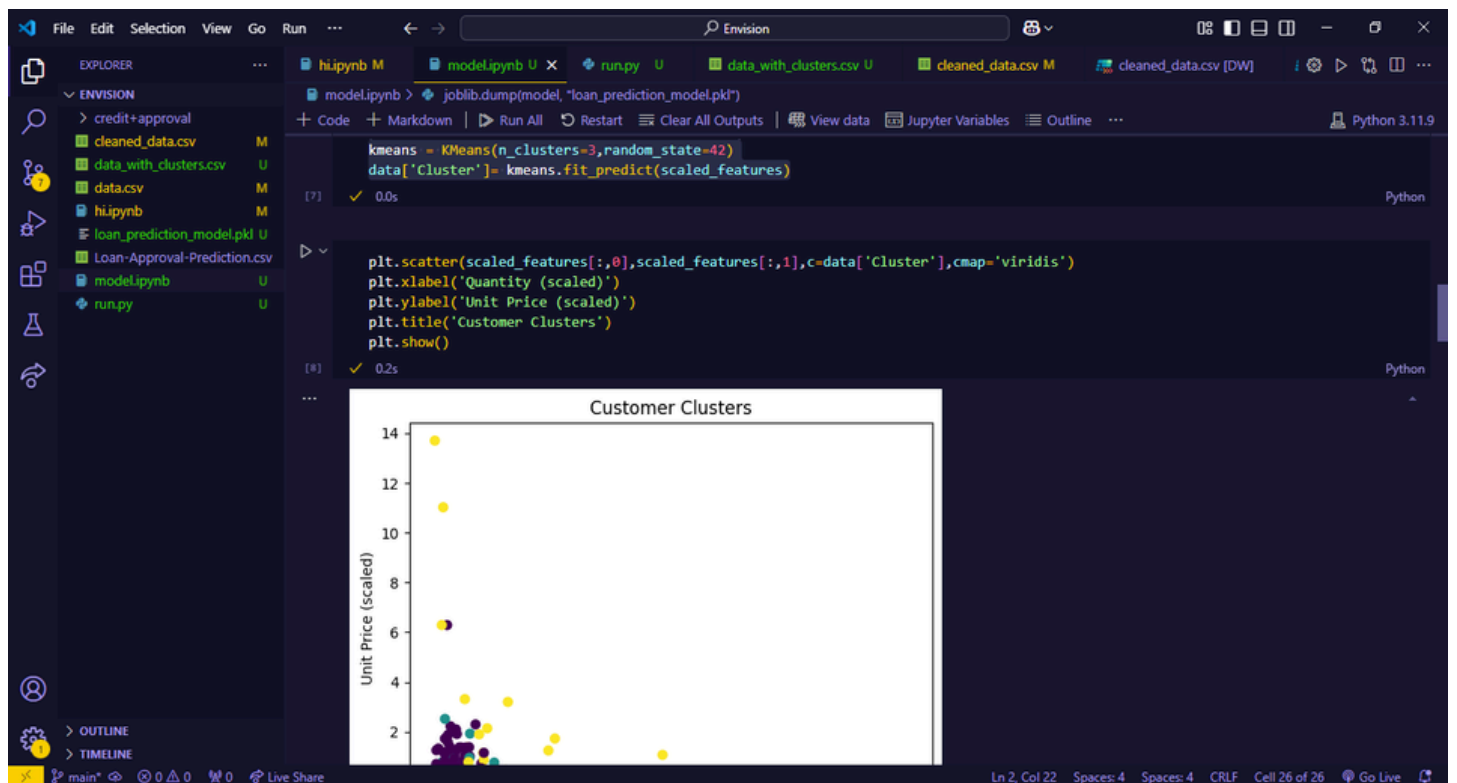

See the caveats in the documentation: https://pandas.pydata.org/pandas-docs/stable/user\_guide/indexing.html#returning-a-view-versus-a-
features['ApplicantIncome'] = features['ApplicantIncome'].astype(float)

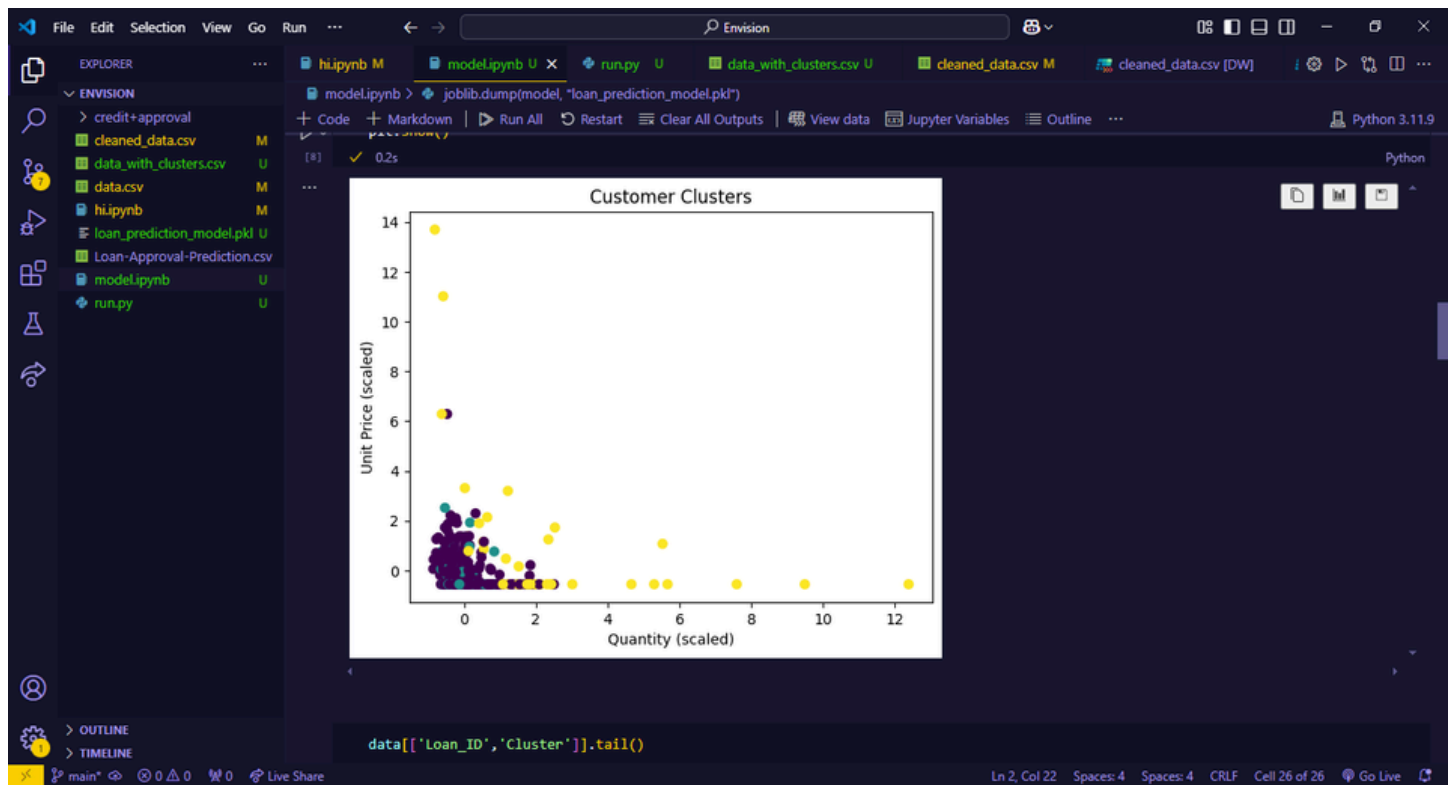

scaler = StandardScaler()
```

Check for number of clusters to be selected and find the optimal number of clusters

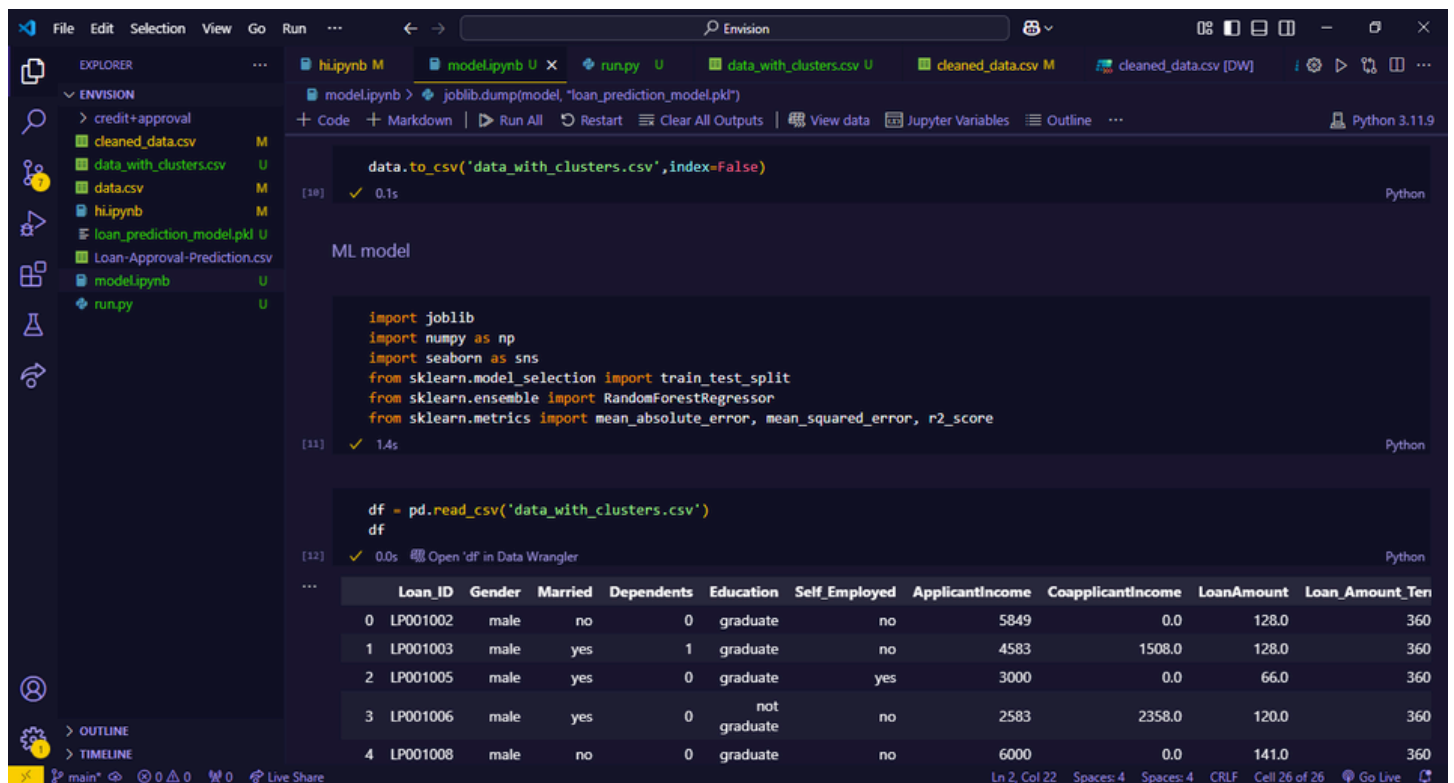

Number of clusters selected = 7

Save clustered data and import ML modules

Label encoded the Categorical data

The screenshot shows the Envision IDE interface with a Python script for data preprocessing. The Explorer panel on the left lists files like `cleaned_data.csv`, `data_with_clusters.csv`, `data.csv`, `hiipynb`, `Loan-Approval-Prediction.csv`, `model.ipynb`, and `run.py`. The main editor displays the following code:

```
df['Gender'] = df['Gender'].map({'male': 1, 'female': 0})
df['Married'] = df['Married'].map({'yes': 1, 'no': 0})
df['Education'] = df['Education'].map({'graduate': 1, 'not graduate': 0})
df['Self_Employed'] = df['Self_Employed'].map({'yes': 1, 'no': 0})
df['Loan_Status'] = df['Loan_Status'].map({'Y': 1, 'N': 0})

le = LabelEncoder()
df['Property_Area'] = le.fit_transform(df['Property_Area'])

print(df.isnull().sum())
df = df.dropna()
```

Below the code, the output of `df.isnull().sum()` is shown as a table:

Loan_ID	0
Gender	0
Married	0
Dependents	0
Education	0
Self_Employed	0
ApplicantIncome	0
CoapplicantIncome	0
LoanAmount	0
Loan_Amount_Term	0
Credit_History	0
Property_Area	0
Loan_Status	0

Train and test the model

The screenshot shows the Envision IDE interface with a Python script for training and testing a Random Forest Regressor model. The Explorer panel on the left lists files like `cleaned_data.csv`, `data_with_clusters.csv`, `data.csv`, `hiipynb`, `Loan-Approval-Prediction.csv`, `model.ipynb`, and `run.py`. The main editor displays the following code:

```
X = df[['Gender', 'Married', 'Education', 'Self_Employed', 'ApplicantIncome', 'CoapplicantIncome', 'LoanAmount', 'Credit_History',
        'Loan_Status']]
Y = df['Loan_Status']

print(X.shape, Y.shape) # Check dimensions of X and Y

X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=0.1, random_state=42)

scaler = StandardScaler()
X_train = scaler.fit_transform(X_train)
X_test = scaler.transform(X_test)

model = RandomForestRegressor(n_estimators=100, random_state=42)
model.fit(X_train, Y_train)
```

Below the code, the output of `print(X.shape, Y.shape)` is shown as a tuple: `(614, 10) (614,)`. The output of `model.fit(X_train, Y_train)` is shown as a `RandomForestRegressor` object with `random_state=42`.

Finding model score

```
Y_pred = model.predict(X_test)

mae = mean_absolute_error(Y_test, Y_pred)
mse = mean_squared_error(Y_test, Y_pred)
rmse = np.sqrt(mse)
r2 = r2_score(Y_test, Y_pred)

print(f"Mean Absolute Error: {mae}")
print(f"Mean Squared Error: {mse}")
print(f"Root Mean Squared Error: {rmse}")
print(f"R² Score: {r2}")

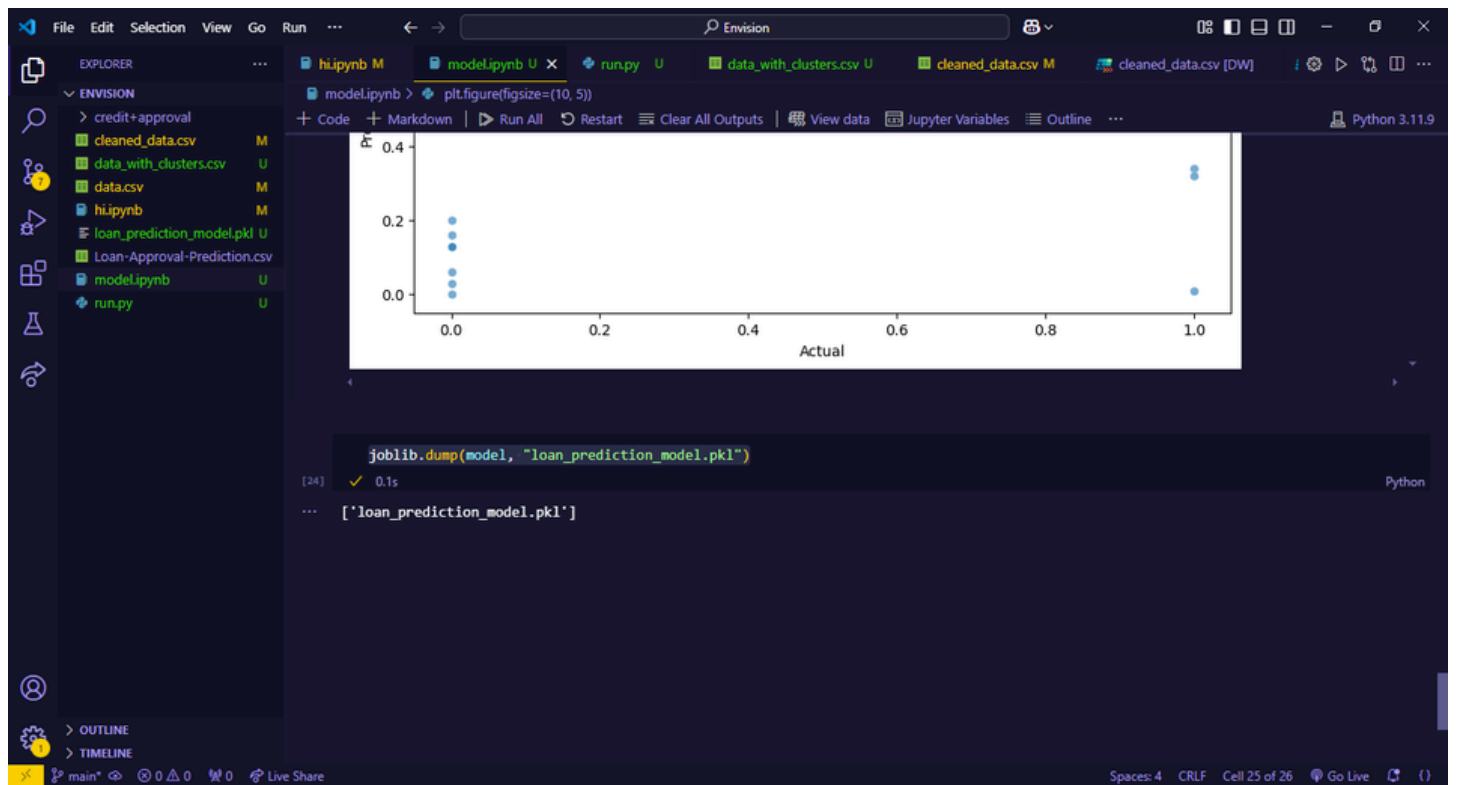

Mean Absolute Error: 0.326774193548387
Mean Squared Error: 0.20760967741935485
Root Mean Squared Error: 0.45564204966108524
R² Score: 0.07311080139372816

plt.figure(figsize=(10, 5))
sns.scatterplot(x=Y_test, y=Y_pred, alpha=0.6)
plt.xlabel("Actual Total Price")
plt.ylabel("Predicted Total Price")
plt.title("Actual vs Predicted Sales")
```

Plotted graph for Actual price VS Predicted

Convert to .pkl file

K-means clustering is a type of unsupervised machine learning algorithm used for partitioning a dataset into K distinct clusters based on their similarities.

Here's a detailed overview:

How K-Means Clustering Works

1. **Initialization**: Choose K random points as centroids.
2. **Assignment**: Assign each data point to the closest centroid.
3. **Update**: Update centroids by calculating the mean of all points assigned to each centroid.
4. **Repeat**: Repeat steps 2-3 until convergence (centroids no longer change).

Key Concepts

1. **Centroid**: The mean of all points in a cluster.
2. **Cluster**: A group of data points with similar characteristics.
3. **Distance Metric**: Measure of similarity between data points (e.g., Euclidean distance).

Advantages:

1. **Easy to Implement**: Simple and intuitive algorithm.
2. **Fast Computation**: Efficient for large datasets.

3. *Effective for Spherical Clusters*: Works well for clusters with similar densities.

Elbow Method is a technique to find the optimal number of clusters (K) in K-Means clustering:

1. Calculate Sum of Squared Errors (SSE) for different K values.

2. Plot SSE against K.

3. Choose K at the "elbow point" where SSE decreases more gradually.

This method helps identify the optimal K value for clustering.

Sales Prediction Model :

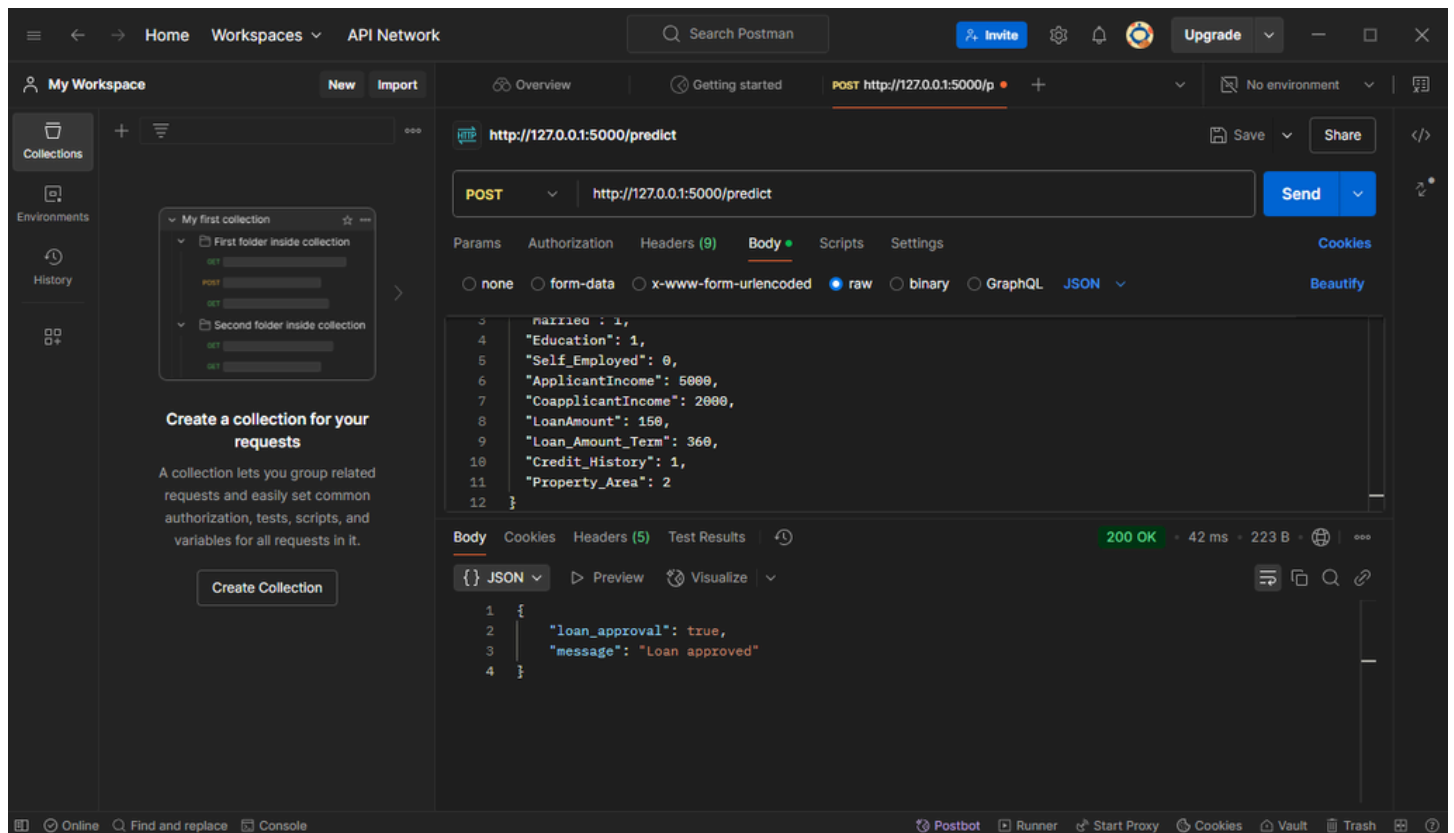

1. Collect historical sales data

2. Preprocess data

3. Choose ML algorithm (e.g., Linear Regression, Random Forest)

4. Train and evaluate model

5. Deploy model for future sales predictions

Deployed locally by PostMan application and tested the prediction model
